# Aberration in the bunching module

acceleration gap of the induction bunching module.

The static and dynamic aberrations for NDCX-I. Pulse t_p=400ns, E_b=300keV, r=1cm, R_w=3.8cm.

$$\frac{\Delta v_{br}}{v_{b0}} \cong \frac{r}{R_w}\left(-\frac{R_w}{4v_{b0}}\frac{e\dot{V}(t)}{E_b} - 0.082\left(\frac{eV(t)}{E_b}\right)^2\right)$$

Strong final focusing element is utilized to reduce spot size at target.

Utilizing a time-dependent Einzel lens for correcting aberrations in the gap and chromatic effects in focusing system is the best. E.P. Lee, private communication (2008). Placing a strong focusing element is the second best.
$r_{sp} \sim r_f \, 2\Delta v_b / v_b$ chromatic effects in the final focusing element

Optimization of the final focus system to achieve minimum of the spot size.
The beam spot radius at the target for two solenoids is given by

$$r_{sp} \sim \frac{r_b \Delta v_b}{v_b} \frac{F_2 F_1 + 2(F_1 - L)^2}{(F_2 + F_1 - L)F_1}$$

Minimizing the final spot size with respect to L,

$$r_{sp,\min} = \frac{r_b \Delta v_b}{v_b} \sqrt{\frac{8F_2}{F_1}} \qquad =1\text{mm}$$

Plasma plug cannot provide sufficient neutrali-zation compared with plasma filling entire volume.

Beam images at the focal plane non-neutralized (a), neutralized plasma plug (b), and volumetric plasma everywhere (c).

P.K. Roy et al, NIMPR. A **544,** 225 (2005).

(a) 1 cm   031002060   FWHM: 2.71 cm

(b) 1 cm   030813016   FWHM: 2.83 mm

(c) 1 cm   030813010   FWHM: 2.14 mm

To determine degree of neutralization electron fluid and *full* Maxwell equations are solved numerically and analytically.

$$\frac{\partial \vec{p}_e}{\partial t} + (\vec{V}_e \bullet \nabla)\vec{p}_e = -\frac{e}{m}(\vec{E} + \frac{1}{c}\vec{V}_e \times \vec{B}), \quad \frac{\partial n_e}{\partial t} + \nabla \bullet \left(n_e \vec{V}_e \right) = 0,$$

$$\nabla \times \vec{B} = \frac{4\pi e}{c}\left(Z_b n_b V_{bz} - n_e V_{ez} \right) + \frac{1}{c}\frac{\partial \vec{E}}{\partial t}, \quad \nabla \times \vec{E} = -\frac{1}{c}\frac{\partial \vec{B}}{\partial t}.$$

Solved analytically for a beam pulse with arbitrary value of n_b/n_p, in 2D, using approximations: fluid approach, conservation of generalized vorticity.

Results of Theory for Self-Electric Field of the Beam Pulse Propagating Through Plasma

Self-electric field is determined by electron inertia ~ electron mass

$$eE_r = \frac{1}{c}V_{ez}B_\theta = -mV_{ez}\frac{\partial V_{ez}}{\partial r} \qquad \phi_{vp} = mV_{ez}^2/2e$$

$$V_{ez} \sim V_b n_b / n_p$$

$$\phi_{vp} = \frac{1}{2}mV_b^2\left(\frac{n_b}{n_p}\right)^2 = 5eV\left(\frac{n_b}{n_p}\right)^2 \qquad \text{NTX K}^+ \text{ 400keV beam} \quad \varphi_b \sim 100V$$

$$(1-f) = \phi_{vp}/\phi_b = 5\%\left(\frac{n_b}{n_p}\right)^2 \qquad \text{Degree of neutralization}$$

Having $n_b \ll n_p$ strongly increases the neutralization degree.

$$F_r = e(E_r - V_b B_\varphi/c) \qquad F_r = -mV_b^2\frac{1}{n_p}\left|\frac{\partial n_b}{\partial r}\right|$$

Magnetic force dominates the electrical force and it is focusing!

Analytic theory of chamber transport: neutralization and excitation of plasma waves by beam depends on bunch duration and plasma frequency, $\omega_p \tau_b$.

magnetic field line

V

magnetic flux surfaces

Small radial electron displacement generates fast poloidal rotation according to conservation of azimuthal canonical momentum:

$$V_\phi = \frac{e}{mc}(A_\phi + B_{sol}\delta r)$$

$$E_r \sim \frac{1}{c}V_{e\phi}B_{sol}$$
The poloidal rotation twists the magnetic field and generates the poloidal magnetic field and large radial electric field.

$$B_{e\varphi} = B_{ez}\frac{V_{e\varphi}}{V_{bz}}$$

I. Kaganovich, et al, PRL **99**, 235002 (2007); PoP (2008).

Equations for Vector Potential in the Slice Approximation.

$$-\frac{1}{r}\frac{\partial}{\partial r}r\frac{\partial}{\partial r}A_z = \frac{4\pi}{c}j_{bz} - \frac{\omega_{pe}^2}{c^2}A_z - \frac{\omega_{ce}}{V_b}\frac{1}{r}\frac{\partial}{\partial r}(rA_\phi).$$

$$-\left(1+\frac{\omega_{ce}^2}{\omega_{pe}^2}\right)\frac{\partial}{\partial r}\left[\frac{1}{r}\frac{\partial}{\partial r}(rA_\phi)\right] = \frac{4\pi}{c}j_{b\phi} - \frac{\omega_{pe}^2}{c^2}A_\phi - \frac{\omega_{ce}}{V_b}\frac{\partial}{\partial r}A_z.$$

The electron return current

New term accounting for departure from quasi-neutrality.

Magnetic dynamo

Electron rotation due to radial displacement

$$\omega_{ce} = \frac{eB_z}{mc}$$

I. Kaganovich, et al, PRL **99**, 235002 (2007).

Applied magnetic field affects self-electromagnetic fields when $\omega_{ce}/\omega_{pe} > V_b/c$

Note increase of fields with applied magnetic field B_{z0}
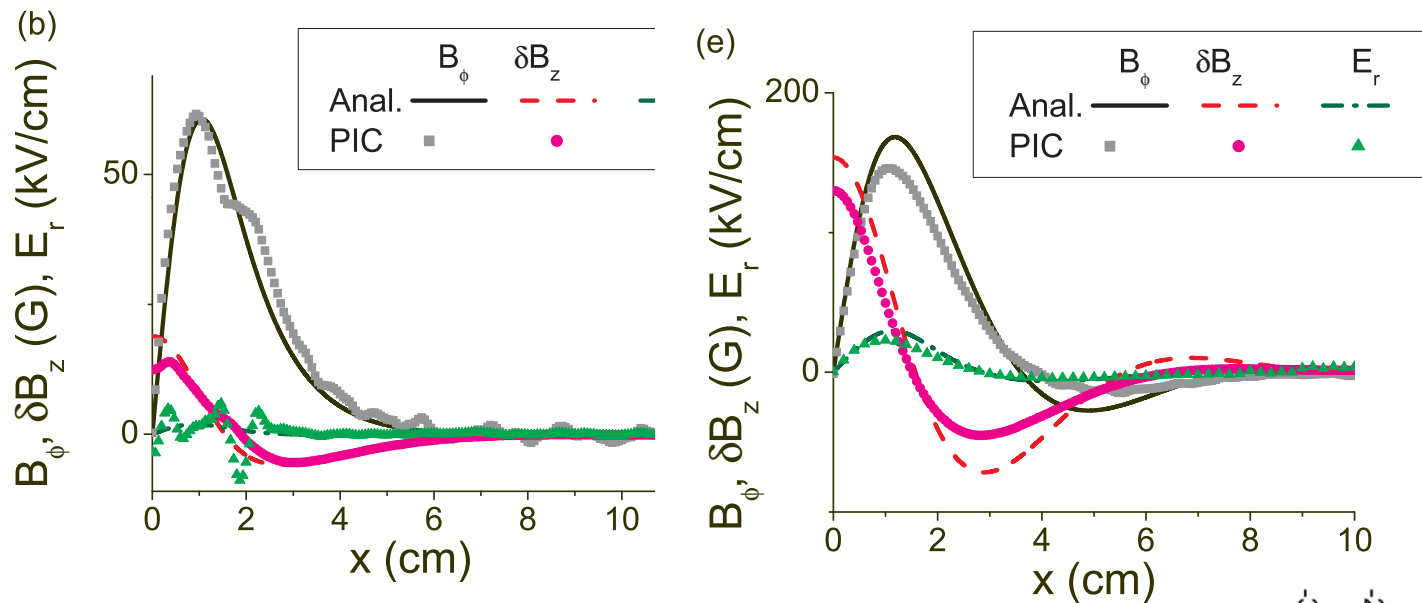

The self-magnetic field; perturbation in the solenoidal magnetic field; and the radial electric field in a perpendicular slice of the beam pulse. The beam parameters are (a) $n_{b0} = n_p/2 = 1.2 \times 10^{11} cm^{-3}$; $V_b =0.33c$, the beam density profile is gaussian. The values of the applied solenoidal magnetic field, B_{z0} are: (b) 300G; and (e) 900G corresponds to $c\omega_{ce}/\bar{V}_b$ $\omega_{pe}=$ (b) 0.57 ; and (e) 1.7.
Application of the solenoidal magnetic field allows control of the radial force acting on the beam ions.
$$F_r = e(E_r - V_b B_\varphi/c),$$
Normalized radial force acting on beam ions in plasma for different values of $(\omega_{ce}/\omega_{pe}\beta_b)^2$. The green line shows a gaussian density profile. $r_b = 1.5\delta_p$; $\delta_p = c/\omega_{pe}$.

I. Kaganovich, et al, PRL **99**, 235002 (2007).

Plasma response to the beam is drastically different depending on $\omega_{ce}/2\beta_b\omega_{pe}$ <1 or >1

Gaussian beam:
$r_b=2c/\omega_{pe}$, $l_b=5r_b$,

β_b =0.33.

Brown line indicate the ion beam pulse.

$$\omega_{ce}/2\beta_b\omega_{pe}$$

V_b

Quasi - electrostatic wave
Conclusions for simultaneous longitudinal and transverse neutralized compression

Identified limiting factors:

errors in the applied velocity tilt compared to the ideal velocity tilt limits the longitudinal compression to 50-100 times.

radial compression is limited by chromatic effects in the focusing system which can be corrected by time-dependent focusing element.

the background plasma can provide the necessary neutralization for compression, provided the plasma density exceeds the beam density everywhere along the beam path, i.e., $n_p > n_b$.

Conclusions for neutralization

Developed a nonlinear theory for the quasi-steady-state propagation of an intense ion beam pulse in a background plasma

> very good charge neutralization: key parameter $\omega_p \, l_b/V_b$,
>
> very good current neutralization: key parameter $\omega_p r_b/c$.

Application of a solenoidal magnetic field can be used for active control of beam transport through a background plasma.

> Theory predicts that there is a sizable enhancement of the self-electric and self-magnetic fields where $\omega_{ce} \sim \beta \omega_{pe}$.
>
> Electromagnetic waves are generated oblique to the direction of the beam propagation where $\omega_{ce} > \beta \omega_{pe}$.

Results of neutralization from 2D PIC Code

Shown are electron density.

Beam propagation in the y-direction, beam length 7.5 c/ω_p; beam radius 1.5 c/ω_p; beam density equals to the half of the plasma density; beam velocity $c/2$.

density
beam length 30. c/ω_p;
beam radius 0.5 c/ω_p;
- **beam density is 5 of plasma density;**
- **beam velocity 0.5c.**
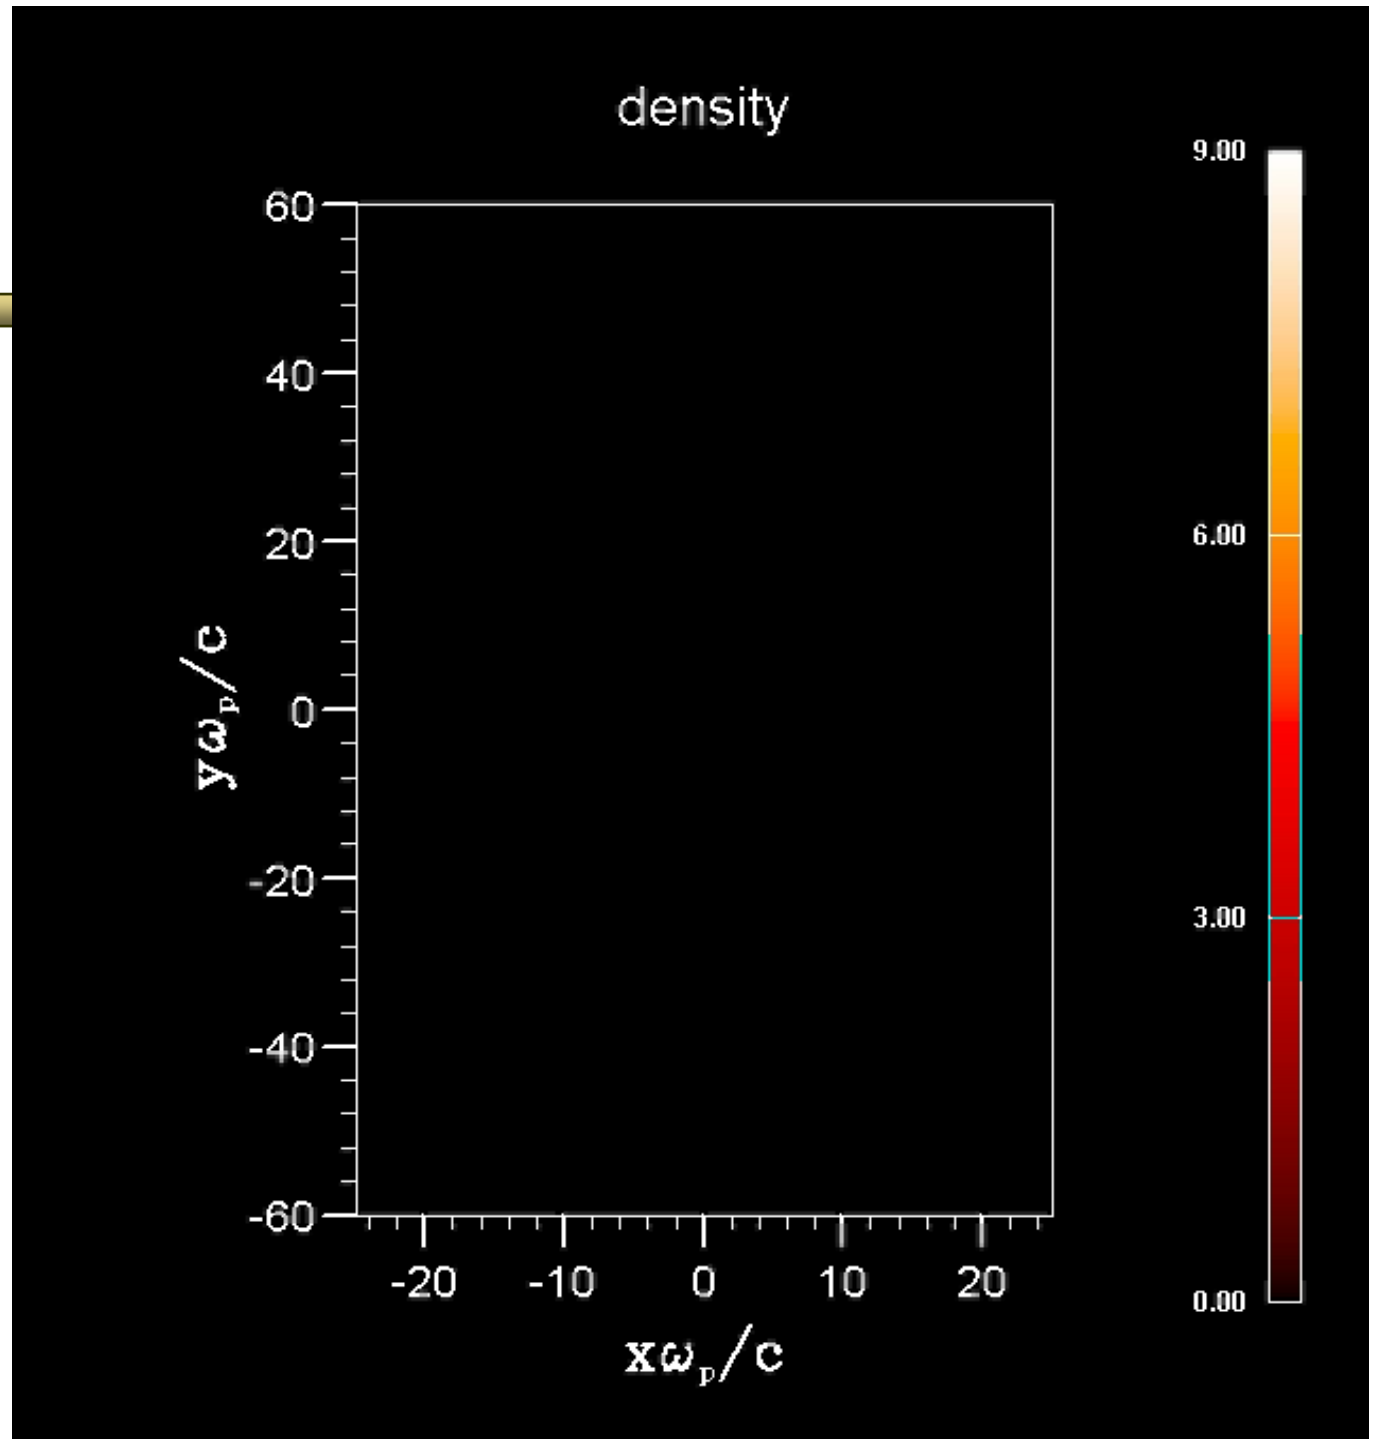

density

Steady- State Results (current flow)

Beam propagates in the y-direction, beam half length l_b=15 c/ω_p ; beam radius r_b =1.5 c/ω_p ; beam density n_b is equal to the background plasma density n_p; beam velocity V_b=c/2.
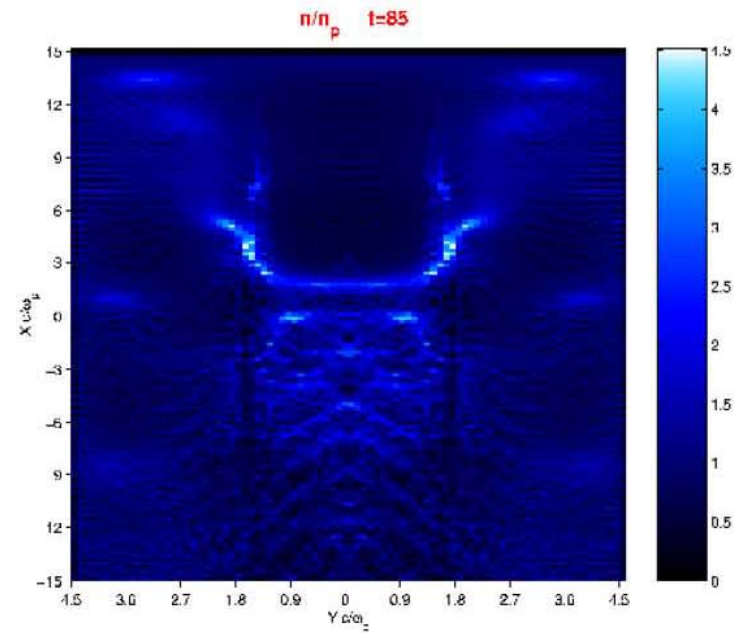

Shown are the normalized electron density n_e/n_p and the vector fields for the current.
