Abstract—Ion beam propagation in a background plasma is an important scientific issue for many practical applications. The process of ion beam charge and current neutralization is complex because plasma electrons move in strong electric and magnetic fields of the beam. Computer simulation images of plasma interaction with an intense ion beam pulse are presented.

The movies produced by visualization of numerical simulation data show complex collective phenomena during beam entry and exit from the plasma [3], [4] and during beam propagation along a solenoidal magnetic field [5]. Note that movies of these results are available online [3], [4].

Fig. 1 shows the electron density perturbation during beam entry into the uniform background plasma in the presence of a solenoidal magnetic field along the beam propagation. Without a solenoidal magnetic field, the wake in the electron density is produced by the ion beam head and lags the ion beam density [1], [4], [7]. Plasma waves form a horizontal stripe pattern in absence of magnetic field. This structure is greatly modified in the presence of an external magnetic field; compare figures in [1], [3] and [7] with Fig. 1. Moreover, a presence of the external solenoidal magnetic field leads to the electron density perturbations propagation ahead of the beam. This makes the moving window computational approach applied for simulations inadequate after certain time when perturbation reach the front boundary [see Fig. 1(d)], as it assumes unperturbed plasma ahead of the beam. The complete study of this phenomena is still in progress and shall be reported in [5] and elsewhere.

Fig. 1. Neutralization of an ion beam pulse during its propagation through a cold, uniform, background plasma in planar geometry with an external uniform magnetic field. Beam propagates in the \( y \)-direction. Beam velocity is \( V_b = 0.5c \), the beam density is \( n_b = 0.5n_p \), where \( n_p \) is the background density, and the ion beam charge state is \( Z_{i+} = 1 \). Beam pulse dimensions are: the beam radius is equal to 1.5 of the skin depth \( (r/c)_{\omega_p} \) and half length is \( 7.5c/\omega_p \). Here, \( \omega_p \) is the electron plasma frequency, \( c \) is the speed of light in vacuum. External magnetic field corresponds to the electron cyclotron frequency \( \omega_{ce} = 5\omega_p \). Shown in the figure are color plots of the normalized density \( (n/n_p) \) obtained in PIC simulations in \((\omega_p x/c, \omega_p y/c)\) space. (a) Beam pulse density (b)–(d) Electron density after beam enters plasma at times: (b) \( 132/\omega_p \), (c) \( 172/\omega_p \), and (d) \( 200/\omega_p \). (e) shows the photograph of the trilobite [6].
